Linear regression

Corso di Laurea Magistrale in Informatica

Università di Roma Tor Vergata

Prof. Giorgio Gambosi

a.a. 2021-2022

Linear models

Linear combination of input features

$$y(\mathbf{x}, \mathbf{w}) = w_0 + w_1 x_1 + w_2 x_2 + ... + w_d x_d$$

with **x** =
$$(x_1, ..., x_d)$$

- Linear function of parameters w
- Linear function of features x

More compactly,

$$y(\mathbf{x}, \mathbf{w}) = \mathbf{w}^T \overline{\mathbf{x}}$$

where
$$\overline{\mathbf{x}} = (1, x_1, \dots, x_d)$$

a.a. 2021-2022 2

Base functions

 \odot Extension to linear combination of base functions ϕ_1, \dots, ϕ_m defined on \mathbb{R}^d

$$y(\mathbf{x}, \mathbf{w}) = \sum_{j=1}^{m} w_j \phi_j(\mathbf{x})$$

- ⊚ Each vector \mathbf{x} in \mathbb{R}^d is mapped to a new vector in \mathbb{R}^m , $\phi(\mathbf{x}) = (\phi_1(\mathbf{x}), ..., \phi_m(\mathbf{x}))$
- \odot the problem is mapped from a *d*-dimensional to an *m*-dimensional space (usually with m > d)

a.a. 2021-2022 3/

Base functions

- Many types:
 - Polynomial (global functions)

$$\phi_i(x) = x^j$$

Gaussian (local)

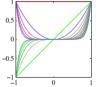

$$\phi_j(x) = \exp\left(-\frac{(x - \mu_j)^2}{2s^2}\right)$$

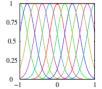

Sigmoid (local)

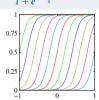

$$\phi_j(x) = \sigma\left(\frac{x - \mu_j}{s}\right) = \frac{1}{1 + e^{-\frac{x - \mu_j}{s}}}$$

• Hyperbolic tangent (local)

$$\phi_j(x) = \tanh(x) = 2\sigma(x) - 1 = \frac{1 - e^{-\frac{x - \mu_j}{s}}}{1 + e^{-\frac{x - \mu_j}{s}}}$$

Base functions

Observe that a set of items (extended by 1 values)

$$\overline{\mathbf{X}} = \begin{pmatrix} - & \overline{\mathbf{x}}_1 & - \\ & \vdots & \\ - & \overline{\mathbf{x}}_n & - \end{pmatrix} = \begin{pmatrix} 1 & x_{11} & \cdots & x_{1d} \\ 1 & x_{21} & \cdots & x_{2d} \\ \vdots & \vdots & \ddots & \vdots \\ 1 & x_{n1} & \cdots & x_{nd} \end{pmatrix}$$

is transformed into

$$\Phi = \left(\begin{array}{cccc} \phi_1(\mathbf{x}_1) & \phi_2(\mathbf{x}_1) & \cdots & \phi_m(\mathbf{x}_1) \\ \phi_1(\mathbf{x}_2) & \phi_2(\mathbf{x}_2) & \cdots & \phi_m(\mathbf{x}_2) \\ \vdots & \vdots & \ddots & \vdots \\ \phi_1(\mathbf{x}_n) & \phi_2(\mathbf{x}_n) & \cdots & \phi_m(\mathbf{x}_n) \end{array} \right)$$

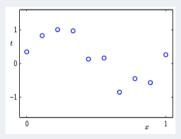

a.a. 2021-2022 5/

Example

Problem

- ⊚ A set of n observations of two variables $x, t \in \mathbb{R}$: $(x_1, t_1), \dots, (x_n, t_n)$) is available. We wish to exploit these observations to predict, for any value \tilde{x} of x, the corresponding unknown value of the target variable t
- \odot The training set is a pair of vectors $\mathbf{x} = (x_1, \dots, x_n)^T$ and $\mathbf{t} = (t_1, \dots, t_n)^T$, related through an unknown rule (function)

Example of a training set.

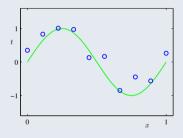

a.a. 2021-2022 6/62

Example

Training set

In this case, we assume that the (unknown) relation between x and t in the training set is provided by the function $t = \sin(2\pi x)$, with an additional gaussian noise with mean 0 and given variance σ^2 . Hence, $t_i = \sin(2\pi x_i) + \varepsilon_i$, with $\varepsilon_i \sim \mathcal{N}(0, \sigma^2)$.

Purpose

Guessing, or approximating as well as possible, the deterministic relation $t = \sin(2\pi x)$, on the basis of the analysis of data in the training set.

a.a. 2021-2022 7/

Approach

Let us approximate the unknown function through a suitable polynomial of given degree m > 0

$$y(x, \mathbf{w}) = w_0 + w_1 x + w_2 x^2 + ... + w_m x_m = \sum_{j=0}^m w_j x^j$$

whose coefficients $\mathbf{w} = (w_0, w_1, \dots, w_m)^T$ are to be computed.

Base functions

This corresponds to applying a set of m+1 base functions $\phi_j(x)=x^j, j=0,\ldots,m$ to the unique feature x

$$y(x, \mathbf{w}) = \sum_{j=0}^{m} w_j \phi_j(x)$$

a.a. 2021-2022 8/6

Base functions and linear models

When base functions are applied, $y(x, \mathbf{w})$ is a nonlinear function of x, but it is still a linear function (model) of \mathbf{w} .

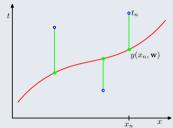

Parameter estimation

The values assigned to coefficients should minimize the empirical risk computed wrt some error function (a.k.a. cost function)

a.a. 2021-2022 9/6

Least squares

A most widely adopted error function is the quadratic loss $(y_i - t_i)^2$, which results into the least quares approach, i.e. minimizing the sum, for all items in the training set, of the (squared) difference between the value returned by the model and the target value.

$$E(\mathbf{w}) = \frac{1}{2} \sum_{i=1}^{n} (y(x_i, \mathbf{w}) - t_i)^2 = \frac{1}{2} \sum_{i=1}^{n} \left(t_i - \sum_{j=0}^{m} w_j \phi_j(x) \right)^2$$

a.a. 2021-2022 10/62

Error minimization

- \odot To minimize $E(\mathbf{w})$, set its derivative w.r.t. \mathbf{w} to $\mathbf{0}$
- the quadratic loss is a convex function, which implies that only one (global) minimum is defined
- \odot $E(\mathbf{w}) = \frac{1}{2} \sum_{i=1}^{n} (y(x_i, \mathbf{w}) t_i)^2$ is convex itself, being the sum of n convex functions $(y(x_k, \mathbf{w}) t_k)^2$
- \odot in particular, $E(\mathbf{w})$ quadratic implies that its derivative is linear, hence that it is zero in one point \mathbf{w}^*

a.a. 2021-2022 11/62

Derivative with respect to

The derivative w.r.t. w is indeed a collection of derivatives. A linear system is obtained:

$$\frac{\partial E(\mathbf{w})}{\partial w_k} = \sum_{i=1}^n \left(y(x_i, \mathbf{w}) - t_i \right) = \sum_{i=1}^n \left(\sum_{j=0}^m w_j \phi_j(x_i) - t_i \right) \phi_k(x_i)$$

Each of the m+1 equations is linear w.r.t. each coefficient in \mathbf{w} . A linear system results, with m+1 equations and m+1 unknowns w_0, \ldots, w_m , which, in general and with the exceptions of degenerate cases, has precisely one solution.

Closed form solution

In this case, the solution is defined in closed form by the normal equations for least squares

$$\mathbf{w}^* = (\Phi^T \Phi)^{-1} \Phi^T \mathbf{t}$$

a.a. 2021-2022 12/6

Gradient descent

- The minimum of $E(\mathbf{w})$ can be computed numerically, by means of gradient descent methods
- Initial assignment $\mathbf{w}^{(0)} = (w_1^{(0)}, w_2^{(0)}, \dots, w_m^{(0)})$, with a corresponding error value

$$E(\mathbf{w}^{(0)}) = \frac{1}{2} \sum_{i=1}^{N} \left(t_i - (\mathbf{w}^{(0)})^T \boldsymbol{\phi}(\mathbf{x}_i) \right)^2$$

- Iteratively, the current value $\mathbf{w}^{(i-1)}$ is modified in the direction of steepest descent of $E(\mathbf{w})$, that is the one corresponding to the negative of the gradient evaluated at $\mathbf{w}^{(i-1)}$
- \odot At step *i*, $w_i^{(i-1)}$ is updated as follows:

$$w_j^{(i)} := w_j^{(i-1)} - \eta \frac{\partial E(\mathbf{w})}{\partial w_j} \bigg|_{\mathbf{w}^{(i-1)}}$$

Gradient descent

In matrix notation:

$$\mathbf{w}^{(i)} := \mathbf{w}^{(i-1)} - \eta \frac{\partial E(\mathbf{w})}{\partial \mathbf{w}} \Big|_{\mathbf{w}^{(i-1)}}$$

 \odot By definition of $E(\mathbf{w})$:

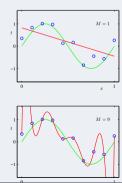

$$\mathbf{w}^{(i)} := \mathbf{w}^{(i-1)} - \eta(t_i - \mathbf{w}^{(i-1)} \boldsymbol{\phi}(\mathbf{x}_i)) \boldsymbol{\phi}(\mathbf{x}_i)$$

Example: fitting of polynomials

Polynomial degree

- Example of model selection: assigning a value to M determines the model to be used, the choice of M implies the number of coefficients to be estimated
- ⊚ increasing *M* allows to better approximate the training set items, decreasing the error
- \odot if M + 1 = n the model allows to obtain a null error (overfitting)

a.a. 2021-2022

Overfitting

- \odot The function $y(x, \mathbf{w})$ is derived from items in the training set, but should provide good predictions for other items.
- It should provide a suitable generalization to all items in the whole domain.
- \odot If $y(x, \mathbf{w})$ is derived as a too much accurate depiction of the training set, it results into an unsuitable generalization to items not in the training set

a.a. 2021-2022 16/6

Evaluation of the generalization

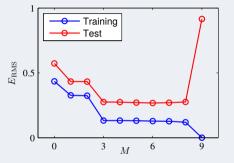

- ⊚ Test set \mathbf{X}_{test} of 100 new items, generated by uniformly sampling x in [0, 1,] and ε from $N(0, \sigma^2)$, and computing $t = \sin 2\pi x + \varepsilon$
- \odot For each M:
 - derives \mathbf{w}^* from the training set \mathbf{X}_{train}
 - compute the error $E(\mathbf{w}^*, \mathbf{X}_{test})$ on the test set, or the square root of its mean

$$E_{RMS}(\mathbf{w}^*, \mathbf{X}_{test}) = \sqrt{\frac{E(\mathbf{w}^*, \mathbf{X}_{test})}{|\mathbf{X}_{test}|}} = \sqrt{\frac{1}{2|\mathbf{X}_{test}|} \sum_{x \in \mathbf{X}_{test}} (y(x, \mathbf{w}) - t)^2}$$

 \odot a lower value of $E_{RMS}(\mathbf{w}^*, \mathbf{X}_{test})$ denotes a good generalization

a.a. 2021-2022 17/62

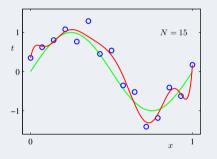

Plot of E_{RMS} w.r.t. M, on the training set and on the test set.

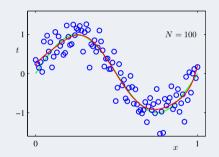

- On the test set, the error initially decreases, since the higher complexity of the model allows to better represent the characteristics of the data set. Next, the error increases, since the model becomes too dependent from the training set: the noise component in t is too represented.

a.a. 2021-2022 18/

For a given model complexity (such as the degree in our example), overfitting decreases as the dimension of the dataset increases.

The larger the dataset, the higher the acceptable complexity of the model.

a.a. 2021-2022 19/62

TAGUA DA Qui in

An estimate of both β_{ML} and the coefficients \mathbf{w}_{ML} can be performed on the basis of the likelihood w.r.t. the assumed normal distribution:

$$L(\mathbf{t}|\mathbf{X}, \mathbf{w}, \beta) = p(\mathbf{t}|\mathbf{X}, \mathbf{w}, \beta) = \prod_{i=1}^{n} N(t_i|y(\mathbf{x}_i, \mathbf{w}), \beta^{-1})$$

Parameters \mathbf{w} and $\boldsymbol{\beta}$ can be estimated as the values which maximize the data likelihood, or its logarithm

$$l(\mathbf{t}|\mathbf{X}, \mathbf{w}, \beta) = \log p(\mathbf{t}|\mathbf{X}, \mathbf{w}, \beta) = \sum_{i=1}^{n} \log N(t_i|y(\mathbf{x}_i, \mathbf{w}), \beta^{-1})$$

which results into

$$l(\mathbf{t}|\mathbf{X},\mathbf{w},\beta) = \sum_{i=1}^{n} \log \left(\frac{\sqrt{\beta}}{\sqrt{2\pi}} e^{-\frac{\beta}{2}(t_i - y(\mathbf{x}_i, \mathbf{w}))^2} \right)$$

$$= -\sum_{i=1}^{n} \frac{\beta}{2} (t_i - y(\mathbf{x}_i, \mathbf{w}))^2 + \frac{n}{2} \log \beta - \frac{n}{2} \log(2\pi)$$

$$= -\frac{\beta}{2} \sum_{i=1}^{n} (t_i - y(\mathbf{x}_i, \mathbf{w}))^2 + \frac{n}{2} \log \beta + \text{cost}$$

Viglo i subri di so tile che la prot, del tapat sia la più atta.

The maximization w.r.t. w is performed by determining a maximum w.r.t. w of the function

$$-\frac{1}{2}\sum_{i=1}^{n}\left(t_{i}-y(\mathbf{x}_{i},\mathbf{w})\right)^{2}$$

this is equivalent to minimizing the least squares sum.

The maximization w.r.t. the precision β is done by setting to 0 the corresponding derivative

$$\frac{\partial l(\mathbf{t}|\mathbf{X}, \mathbf{w}, \beta)}{\partial \beta} = -\frac{1}{2} \sum_{i=1}^{n} (t_i - y(\mathbf{x}_i, \mathbf{w}))^2 + \frac{n}{2\beta}$$

which results into

$$\beta_{ML}^{-1} = \frac{1}{n} \sum_{i=1}^{n} (t_i - y(\mathbf{x}_i, \mathbf{w}))^2$$

a.a. 2021-2022 32/62

As a side result, the parameter estimate provides a predictive distribution of t given \mathbf{x} , that is the (gaussian) distribution of the target value for a given item \mathbf{x} .

$$p(t|\mathbf{x}; \mathbf{w}, \beta) = \mathcal{N}(t|y(\mathbf{x}, \mathbf{w}), \beta^{-1}) = \sqrt{\frac{\beta_{ML}}{2\pi}} e^{-\frac{\beta_{ML}}{2}(t - y(\mathbf{x}, \mathbf{w}_{ML}))^2}$$

a.a. 2021-2022 33/6

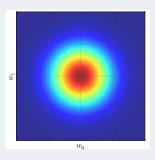

- In the maximum likelihood framework parameters are considered as (unknown) values to determine with the best possible precision (frequentist approach).
- \odot Applying maximum likelihood to determine the values of model parameters is prone to overfitting: need of a regularization term $E(\mathbf{w})$.
- In order control model complexity, a bayesian approach assumes a prior distribution of parameter values.
- The bayesian framework looks at parameters as random variables, whose probability distribution has to be derived.

a.a. 2021-2022 34/6

Probabilistic model for regression

Prior distribution of parameters: gaussian with mean ${\bf 0}$ and diagonal covariance matrix with variance equal to the inverse of hyperparameter α

$$p(\mathbf{w}|\alpha) = \mathcal{N}(\mathbf{w}|\mathbf{0}, \alpha^{-1}\mathbf{I}) = \left(\frac{\alpha}{2\pi}\right)^{\frac{m+1}{2}} e^{-\frac{\alpha}{2}\mathbf{w}^T\mathbf{w}}$$

a.a. 2021-2022 35/62

Posterior proportional to prior times likelihood: likelihood is gaussian (gaussian noise).

$$p(\mathbf{t}|\Phi, \mathbf{w}, \beta) = \prod_{i=1}^{n} \mathcal{N}(t_i|\mathbf{w}^T \phi(\mathbf{x}_i), \beta^{-1}) = \prod_{i=1}^{n} e^{-\frac{\beta}{2}(t_i - \mathbf{w}^T \phi(\mathbf{x}_i))^2}$$

Given the prior $p(\mathbf{w}|\alpha)$, the posterior distribution for \mathbf{w} derives from Bayes' rule

$$p(\mathbf{w}|\mathbf{t}, \Phi, \alpha, \sigma) = \frac{p(\mathbf{t}|\Phi, \mathbf{w}, \sigma)p(\mathbf{w}|\alpha)}{p(\mathbf{t}|\Phi, \alpha, \sigma)} \propto p(\mathbf{t}|\Phi, \mathbf{w}, \sigma)p(\mathbf{w}|\alpha)$$

a.a. 2021-2022 36/6

In general, conjugate of gaussian is gaussian: choosing a gaussian prior distribution of \mathbf{w}

$$p(\mathbf{w}) = \mathcal{N}(\mathbf{w}|\mathbf{m}_0, \Sigma_0)$$

results into a gaussian posterior distribution

$$p(\mathbf{w}|\mathbf{t}, \Phi) = \mathcal{N}(\mathbf{w}|\mathbf{m}_p, \Sigma_p)$$

where

$$\Sigma_p = (\Sigma_0^{-1} + \beta \Phi^T \Phi)^{-1}$$
$$\mathbf{m}_p = \Sigma_p (\Sigma_0^{-1} \mathbf{m}_0 + \beta \Phi^T \mathbf{t})$$

a.a. 2021-2022 37/6

Here, we have

$$p(\mathbf{w}) = \mathcal{N}(\mathbf{w}|\mathbf{0}, \alpha^{-1}\mathbf{I}) \qquad p(\mathbf{t}|\mathbf{w}, \Phi) = \mathcal{N}(\mathbf{t}|\mathbf{w}^T \Phi, \beta^{-1}\mathbf{I})$$

and the posterior distribution is gaussian

$$p(\mathbf{w}|\mathbf{t}, \Phi, \alpha, \sigma) = \mathcal{N}(\mathbf{w}|\mathbf{m}_p, \Sigma_p)$$

with

$$\Sigma_p = (\alpha \mathbf{I} + \beta \Phi^T \Phi)^{-1} \qquad \mathbf{m}_p = \beta \Sigma_p \Phi^T \mathbf{t}$$

a.a. 2021-2022 38/

Note that as $\alpha \to 0$ the prior tends to have infinite variance, and we have minimum information on **w** before the training set is considered. In this case,

$$\mathbf{m}_p \to (\Phi^T \Phi)^{-1} (\Phi^T \mathbf{t})$$

that is \mathbf{w}_{ML} , the ML estimation of \mathbf{w} .

a.a. 2021-2022 39 /

Maximum a Posteriori

- © Given the posterior distribution $p(\mathbf{w}|\Phi, \mathbf{t}, \alpha, \beta)$, we may derive the value of \mathbf{w}_{MAP} which makes it maximum (the mode of the distribution)
- This is equivalent to maximizing its logarithm

$$\log p(\mathbf{w}|\Phi, \mathbf{t}, \alpha, \beta) = \log p(\mathbf{t}|\mathbf{w}, \Phi, \beta) + \log p(\mathbf{w}|\alpha) - \log p(\mathbf{t}|\Phi, \beta)$$

and, since $p(\mathbf{t}|\Phi,\beta)$ is a constant wrt **w**

$$\mathbf{w}_{MAP} = \underset{\mathbf{w}}{\operatorname{argmax}} \ \log p(\mathbf{w}|\Phi, \mathbf{t}, \alpha, \beta) = \underset{\mathbf{w}}{\operatorname{argmax}} \ (\log p(\mathbf{t}|\mathbf{w}, \Phi, \beta) + \log p(\mathbf{w}|\alpha))$$

that is,

$$\mathbf{w}_{MAP} = \underset{\mathbf{w}}{\operatorname{argmin}} \ (-\log p(\mathbf{t}|\Phi, \mathbf{w}, \beta) - \log p(\mathbf{w}|\alpha))$$

a.a. 2021-2022 40/62

Maximum a Posteriori

In this case

$$p(\mathbf{w}|\mathbf{X}, \mathbf{t}; \alpha, \beta) \propto p(\mathbf{t}|\mathbf{X}, \mathbf{w}; \beta) p(\mathbf{w}|\alpha)$$

$$= \prod_{i=1}^{n} \left(\frac{\sqrt{\beta}}{\sqrt{2\pi}} e^{-\frac{\beta}{2} (t_i - y(\mathbf{x}_i, \mathbf{w}))^2} \right) \left(\frac{\alpha}{2\pi} \right)^{\frac{M+1}{2}} e^{-\frac{\alpha}{2} \mathbf{w}^T \mathbf{w}}$$

The maximization of the posterior distribution (MAP) is equivalent to the maximization of the corresponding logarithm

$$-\frac{\beta}{2}\sum_{i=1}^{n}\left(t_{i}-y(\mathbf{x}_{i},\mathbf{w})\right)^{2}+\frac{n}{2}\log\beta-\frac{\alpha}{2}\mathbf{w}^{T}\mathbf{w}+\frac{m+1}{2}\log\frac{\alpha}{2\pi}+\mathrm{cost}$$

The value \mathbf{w}_{MAP} which maximize the probability (mode of the distribution) also minimizes

$$\frac{\beta}{2} \sum_{i=1}^{n} (t_i - y(\mathbf{x}_i, \mathbf{w}))^2 + \frac{\alpha}{2} \mathbf{w}^T \mathbf{w} = \beta \left(\frac{1}{2} \sum_{i=1}^{n} (t_i - y(\mathbf{x}_i, \mathbf{w}))^2 + \frac{\alpha}{2\beta} ||\mathbf{w}||^2 \right)$$

The ratio $\frac{\alpha}{\beta}$ corresponds to a regularization hyperparameter.

a.a. 2021-2022 41/

Maximum a Posteriori

The same considerations of ML appy here for what concerns deriving the predictive distribution of t given x, which results now

$$p(t|\mathbf{x}; \mathbf{w}, \beta_{MAP}) = \mathcal{N}(t|y(\mathbf{x}, \mathbf{w}), \beta_{MAP}^{-1}) = \sqrt{\frac{\beta_{MAP}}{2\pi}} e^{-\frac{\beta_{MAP}}{2} (t - y(\mathbf{x}, \mathbf{w}_{MAP}))^2}$$

where, as it is easy to see, $\beta_{MAP} = \beta_{ML}$

a.a. 2021-2022 42/6

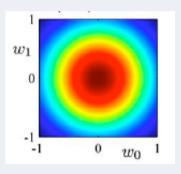

Sequential learning

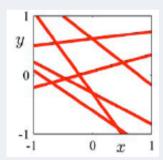

- \odot The posterior after observing T_1 can be used as a prior for the next training set acquired.
- \odot In general, for a sequence T_1, \dots, T_n of training sets,

$$\begin{aligned} p(\mathbf{w}|T_1, \dots T_n) &\propto p(T_n|\mathbf{w})p(\mathbf{w}|T_1, \dots T_{n-1}) \\ p(\mathbf{w}|T_1, \dots T_{n-1}) &\propto p(T_{n-1}|\mathbf{w})p(\mathbf{w}|T_1, \dots T_{n-2}) \\ \dots \\ p(\mathbf{w}|T_1) &\propto p(T_1|\mathbf{w})p(\mathbf{w}) \end{aligned}$$

a.a. 2021-2022 43/

- ⊚ Input variable x, target variable t, linear regression $y(x, w_0, w_1) = w_0 + w_1 x$.
- ⊚ Dataset generated by applying function $y = a_0 + a_1 x$ (with $a_0 = -0.3$, $a_1 = 0.5$) to values uniformly sampled in [-1, 1], with added gaussian noise ($\mu = 0$, $\sigma = 0.2$).
- \odot Assume the prior distribution $p(w_0, w_1)$ is a bivariate gaussian with $\mu = 0$ and $\Sigma = \sigma^2 \mathbf{I} = 0.04 \mathbf{I}$

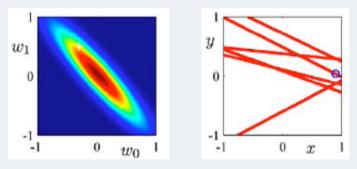

Left, prior distribution of w_0 , w_1 ; right, 6 lines sampled from the distribution.

a.a. 2021-2022 44/62

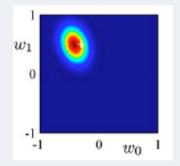

After observing item (x_1, y_1) (circle in right figure).

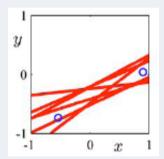

Left, posterior distribution $p(w_0, w_1|x_1, y_1)$; right, 6 lines sampled from the distribution.

a.a. 2021-2022 45/

After observing items $(x_1, y_1), (x_2, y_2)$ (circles in right figure).

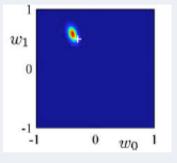

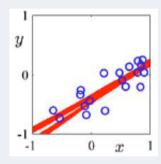

Left, posterior distribution $p(w_0, w_1|x_1, y_1, x_2, y_2)$; right, 6 lines sampled from the distribution.

a.a. 2021-2022 46/62

After observing a set of *n* items $(x_1, y_1), \dots, (x_n, y_n)$ (circles in right figure).

Left, posterior distribution $p(w_0, w_1|x_i, y_i, i = 1, ..., n)$; right, 6 lines sampled from the distribution.

a.a. 2021-2022 47/62

- \odot As the number of observed items increases, the distribution of parameters w_0, w_1 tends to concentrate (variance decreases to 0) around a mean point a_0, a_1 .
- \odot As a consequence, sampled lines are concentrated around $y = a_0 + a_1 x$.

a.a. 2021-2022 48/62

Classical

- \odot A value \mathbf{w}_{LS} for \mathbf{w} is learned through a point estimate, performed by minimizing a quadratic cost function, or equivalently by maximizing likelihood (ML) under the hypothesis of gaussian noise; regularization can be applied to modify the cost function to limit overfitting
- ① Given any \mathbf{x} , the obtained value \mathbf{w}_{LS} is used to predict the corresponding t as $y = \overline{\mathbf{x}}^T \mathbf{w}_{LS}$, where $\overline{\mathbf{x}}^T = (1, \mathbf{x})^T$, or, in general, as $y = \phi(\mathbf{x})^T \mathbf{w}_{LS}$

a.a. 2021-2022 49/6

Bayesian point estimation

- \odot The posterior distribution $p(\mathbf{w}|\mathbf{t}, \Phi, \alpha, \beta)$ is derived and a point estimate is performed from it, computing the mode \mathbf{w}_{MAP} of the distribution (MAP)
- \odot Equivalent to the classical approach, as \mathbf{w}_{MAP} corresponds to \mathbf{w}_{LS} if $\lambda=rac{lpha}{eta}$
- ⊚ The prediction, for a value \mathbf{x} , is a gaussian distribution $p(y|\phi(\mathbf{x})^T\mathbf{w}_{MAP}, \beta)$ for y, with mean $\phi(\mathbf{x})^T\mathbf{w}_{MAP}$ and variance β^{-1}
- \odot The distribution is not derived directly from the posterior $p(\mathbf{w}|\mathbf{t}, \Phi, \alpha, \beta)$: it is built, instead, as a gaussian with mean depending from the expectation of the posterior, and variance given by the assumed noise.

a.a. 2021-2022 50/6

Fully bayesian

The real interest is not in estimating w or its distribution $p(\mathbf{w}|\mathbf{t}, \Phi, \alpha, \beta)$, but in deriving the predictive distribution $p(y|\mathbf{x})$. This can be done through expectation of the probability $p(y|\mathbf{x}, \mathbf{w}, \beta)$ predicted by a model instance wrt model instance distribution $p(\mathbf{w}|\mathbf{t}, \Phi, \alpha, \beta)$, that is

$$p(y|\mathbf{x}, \mathbf{t}, \Phi, \alpha, \beta) = \int p(y|\mathbf{x}, \mathbf{w}, \beta) p(\mathbf{w}|\mathbf{t}, \Phi, \alpha, \beta) d\mathbf{w}$$

 $oldsymbol{\circ} p(y|\mathbf{x},\mathbf{w},\beta)$ is assumed gaussian, and $p(\mathbf{w}|\mathbf{t},\Phi,\alpha,\beta)$ is gaussian by the assumption that the likelihood $p(\mathbf{t}|\mathbf{w},\Phi,\beta)$ and the prior $p(\mathbf{w}|\alpha)$ are gaussian themselves and by their being conjugate

$$\begin{split} p(y|\mathbf{x}, \mathbf{w}, \beta) &= \mathcal{N}(y|\mathbf{w}^T \boldsymbol{\phi}(\mathbf{x}), \beta) \\ p(\mathbf{w}|\mathbf{t}, \Phi, \alpha, \beta) &= \mathcal{N}(\mathbf{w}|\beta \mathbf{S}_N \Phi^T \mathbf{t}, \mathbf{S}_N) \end{split}$$

where
$$\mathbf{S}_N = (\alpha \mathbf{I} + \beta \Phi^T \Phi)^{-1}$$

Fully bayesian

Under such hypothesis, $p(y|\mathbf{x})$ is gaussian

$$p(y|\mathbf{x}, \mathbf{y}, \Phi, \alpha, \beta) = \mathcal{N}(y|m(\mathbf{x}), \sigma^2(\mathbf{x}))$$

with mean

$$m(\mathbf{x}) = \beta \phi(\mathbf{x})^T \mathbf{S}_N \Phi^T \mathbf{t}$$

and variance

$$\sigma^2(\mathbf{x}) = \frac{1}{\beta} + \boldsymbol{\phi}(\mathbf{x})^T \mathbf{S}_N \boldsymbol{\phi}(\mathbf{x})$$

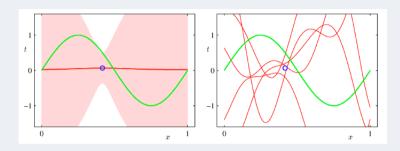

- \odot $\frac{1}{\beta}$ is a measure of the uncertainty intrinsic to observed data (noise)
- \circ $\phi(\mathbf{x})^T \mathbf{S}_N \phi(\mathbf{x})$ is the uncertainty wrt the values derived for the parameters \mathbf{w}
- \odot as the noise distribution and the distribution of \mathbf{w} are independent gaussians, their variances add
- $\phi(\mathbf{x})^T \mathbf{S}_N \phi(\mathbf{x}) \to 0$ as $n \to \infty$, and the only uncertainty remaining is the one intrinsic into data observation

a.a. 2021-2022 52/

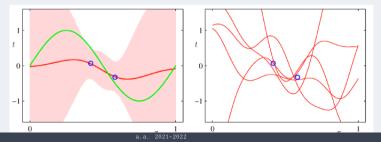

- \odot predictive distribution for $y = \sin 2\pi x$, applying a model with 9 gaussian base functions and training sets of 1, 2, 4, 25 items, respectively
- left: items in training sets (sampled uniformly, with added gaussian noise); expectation of the predictive distribution (red), as function of x; variance of such distribution (pink shade within 1 standard deviation from mean), as a function of x
- \odot right: items in training sets, 5 possible curves approximating $y = \sin 2\pi x$, derived through sampling from the posterior distribution $p(\mathbf{w}|\mathbf{t}, \Phi, \alpha, \beta)$

a.a. 2021-2022 53/6

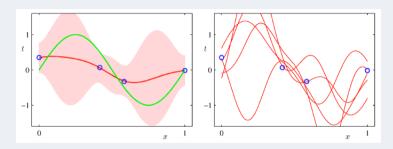

$$n = 1$$

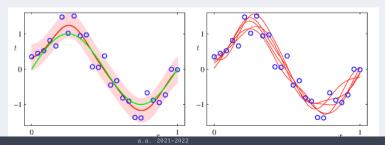

n = 25

Fully bayesian regression and hyperparameter marginalization

 \odot In a fully bayesian approach, also the hyper-parameters α , β are marginalized

$$p(t|\mathbf{x}, \mathbf{t}, \Phi) = \int p(t|\mathbf{x}, \mathbf{w}, \beta) p(\mathbf{w}|\mathbf{t}, \Phi, \alpha, \beta) p(\alpha, \beta|\mathbf{t}, \Phi) d\mathbf{w} d\alpha d\beta$$

where, as seen before,

•
$$p(t|\mathbf{x}, \mathbf{w}, \beta) = \mathcal{N}(t|\mathbf{w}^T \phi(\mathbf{x}), \beta)$$

• $p(\mathbf{w}|\mathbf{t}, \Phi, \alpha, \beta) = \mathcal{N}(\mathbf{w}|\mathbf{m}_N, \mathbf{S}_N)$, with $\mathbf{S}_N = (\alpha \mathbf{I} + \beta \Phi^T \Phi)^{-1}$ e $\mathbf{m}_N = \beta \mathbf{S}_N \Phi^T \mathbf{t}$

this marginalization wrt $\mathbf{w}, \alpha, \beta$ is analytically intractable

 \odot we may consider an approximation where point estimation is applied to derive hyper-parameter values by maximizing the posterior distribution $p(\alpha, \beta | \mathbf{t}, \Phi)$

a.a. 2021-2022 56/62

Fully bayesian regression and hyperparameter marginalization

 \odot since $p(\alpha, \beta | \mathbf{t}, \Phi) \propto p(\mathbf{t} | \Phi, \alpha, \beta) p(\alpha, \beta)$, if we assume that $p(\alpha, \beta)$ is relatively flat, then

$$\underset{\alpha,\beta}{\operatorname{argmax}} \ p(\alpha,\beta|\mathbf{t},\Phi) \simeq \underset{\alpha,\beta}{\operatorname{argmax}} \ p(\mathbf{t}|\Phi,\alpha,\beta)$$

and we may consider the maximization of the marginal likelihood (marginal wrt to coefficients w)

$$p(\mathbf{t}|\Phi,\alpha,\beta) = \int p(\mathbf{t}|\mathbf{w},\Phi,\beta)p(\mathbf{w}|\alpha)d\mathbf{w}$$

 \odot if we assume that $p(\Phi)$ is constant this is equivalent to maximize the evidence

$$p(\Phi, \mathbf{t}|\alpha, \beta) = p(\mathbf{t}|\Phi, \alpha, \beta)p(\Phi|\alpha, \beta) \propto p(\mathbf{t}|\Phi, \alpha, \beta)$$

a.a. 2021-2022 57/

The expectation of the predictive distribution can be written as

$$y(\mathbf{x}) = \beta \phi(\mathbf{x})^T \mathbf{S}_N \Phi^T \mathbf{t} = \sum_{i=1}^n \beta \phi(\mathbf{x})^T \mathbf{S}_N \phi(\mathbf{x}_i) t_i$$

The prediction can be seen as a linear combination of the target values t_i of items in the training set, with weights dependent from the item values \mathbf{x}_i (and from \mathbf{x})

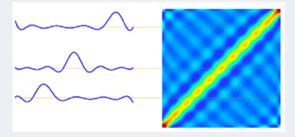

$$y(\mathbf{x}) = \sum_{i=1}^{n} \kappa(\mathbf{x}, \mathbf{x}_i) t_i$$

The weight function $\kappa(\mathbf{x}, \mathbf{x}') = \beta \phi(\mathbf{x})^T \mathbf{S}_N \phi(\mathbf{x}')$ is said equivalent kernel

a.a. 2021-2022 58/62

Right: plot on the plane (x, x_i) of a sample equivalent kernel, in the case of gaussian basis functions.

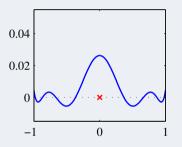

Left: plot as a function of x_i for three different values of x

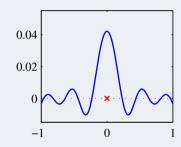

In deriving y, the equivalent kernel tends to assign greater relevance to the target values t_i corresponding to items x_i near to x.

a.a. 2021-2022 59/62

The same localization property holds also for different base functions.

Left, $\kappa(0, x')$ in the case of polynomial basis functions.

Right, $\kappa(0, x')$ in the case of gaussian basis functions.

a.a. 2021-2022 60/6

 \odot The covariance between $y(\mathbf{x})$ and $y(\mathbf{x}')$ is given by

$$\mathrm{cov}(\mathbf{x},\mathbf{x}') = \mathrm{cov}(\pmb{\phi}(\mathbf{x})^T\mathbf{w},\mathbf{w}^T\pmb{\phi}(\mathbf{x}')) = \Phi(\mathbf{x})^T\mathbf{S}_N\pmb{\phi}(\mathbf{x}') = \frac{1}{\beta}\kappa(\mathbf{x},\mathbf{x}')$$

predicted values are highly correlated at nearby points.

- Instead of introducing base functions which results into a kernel, we may define a localized kernel directly
 and use it to make predictions (this is the case of gaussian processes)
- © The equivalent kernel can be expressed as inner product $\kappa(\mathbf{x}, \mathbf{x}') = \psi(\mathbf{x})^T \psi(\mathbf{x}')$ of a suitable set of functions

$$\psi(\mathbf{x}) = \beta^{1/2} \mathbf{S}_N^{1/2} \phi(\mathbf{x})$$

a.a. 2021-2022 61/6

Alternative approach to linear regression

- First approach: define a set of base functions
 - used to derive w
 - or (by means of the resulting equivalent kernel) to directly computing $y(\mathbf{x})$ as a linear combination of training set items
- \odot New approach: a suitable kernel is defined and used to compute $y(\mathbf{x})$

a.a. 2021-2022 62/6
